Editor's Note: *EarthBeat Weekly is your weekly newsletter about faith and climate change. Below is the Nov. 13 edition. To receive EarthBeat Weekly in your inbox, [sign up here](#).*

There's no question that humans have adapted to live in some pretty extreme environments.

A few years ago, I visited an archaeological site 14,700 feet high in the Andes Mountains where people lived some 12,000 years ago. That's nearly three miles up! And it's still one of the earliest known sites of human habitation that high, in a rock shelter well above the tree line.

Some time earlier, I'd stood on the beach on an island off the southern tip of South America, where ancient inhabitants dove into the frigid water to gather shellfish, with only a layer of seal fat smeared on their skin for protection. I contemplated that while bundled against a freezing wind, watching chunks of ice floating in the bay.

And of course even today there are communities of original peoples in the Arctic and desert dwellers in the Sahara. But [a recent study of human habitation over the past six millennia](#) found that for the most part, we've settled into places on the globe where the average temperature lies mainly in the 50s degrees Fahrenheit range — between 11 and 15 degrees Celsius.

That seems to be the optimal temperature range for people, their crops, their livestock and even non-agricultural economic activity. And temperature, even more than precipitation, appears to be most decisive in this pattern of population concentration.

So what will happen as temperatures rise with a changing climate?

The authors of the study, which was published in May by the Proceedings of the National Academy of Sciences in the U.S., point out that the "Goldilocks" zone — not too hot, not too cold — will shrink and shift toward the poles — northward in the

northern hemisphere, and southward in the southern, until it nearly disappears altogether.

Parts of the world that are now densely inhabited, where the average temperature is around 55 F, will find the average rising to about 68 F. Although that is still comfortable for humans, it is a radical change for some crops — as [coffee farmers in Central America](#) are already finding. And "average" means some days will see far higher temperature spikes.

The areas with the highest temperatures are also the places where the greatest population growth is predicted, so more people will be living in places that already test the limits of human endurance and agricultural production.

Under the "business-as-usual" scenario, without substantial reduction of greenhouse gas emissions, the authors estimate that by 2070, some 3.5 billion people would be left out of the "geographical niche" of that optimal temperature where humans have chosen to settle for millennia. With mitigation efforts to reduce emissions, that could be reduced to about 1.5 billion, they say.

Will those people be able to adapt to the higher temperatures where they live, or will they migrate toward cooler areas? What would the consequences be for livelihoods and food supplies, among other things?

The authors of the study recognize that human migration is the result of many factors, but the potential ferocity of temperature increases and a shrinking, shifting area ideal for human habitation on the planet should give us plenty of reason to take seriously the call for net-zero emissions — the point at which no more human-caused emissions accumulate in the atmosphere — as soon as possible.

The 26th U.N. climate summit was to have started this week, but [was postponed](#) until November 2021 because of the coronavirus pandemic. I spoke this week with various advocates who said clearly that the urgent task of implementing — and working toward — stricter emission-reduction targets cannot wait another year.

They highlighted [priorities for this "gap year" until the next summit](#) — more ambitious emissions-reduction targets by 2030, and more financing and technical assistance to help lower-income countries (many of them in that already-warming belt, or threatened by rising sea level) convert from fossil fuels to renewable energy and adapt to the changes.

What could rising temperatures mean for population movement in the United States? At ProPublica, they've created a series of animated maps that provide a [sobering, graphic overview of the shrinking, shifting comfort zone](#). Lucas Waldron and Abraham Lustgarten note that people are still moving to cities in the areas that are expected to become least habitable. That is unlikely to be sustainable.

"Ultimately, millions of people will be displaced by flooding, fires and scorching heat, a resorting of the map not seen since the Dust Bowl of the 1930s," they write. "Now as then, the biggest question will be who escapes and who is left behind."

Here's what else is new on EarthBeat this week:

- Catholic and environmental activists hope that President-elect Joe Biden's administration will [shift U.S. climate policy](#) after four years of inaction under President Donald Trump, despite the likelihood of a legislative impasse if Republicans retain control of the U.S. Senate. NCR environment correspondent Brian Roewe has the story.
- Chris Herlinger of Global Sisters Report notes that sisters who represent religious organizations at the United Nations were among those who [welcomed the news](#) of the victory of Biden and Vice President-elect Kamala Harris, who have pledged to return the U.S. to both the Paris Agreement on climate change and the World Health Organization.
- [Pope Francis called Biden](#) on Thursday, and among the topics they discussed was "addressing the crisis of climate change," reports NCR national correspondent Christopher White.
- The pope already has a hydrogen-powered popemobile that emits only water vapor, and now the Vatican is planning to [replace its entire fleet of service vehicles with electric models](#), reports Carol Glatz for Catholic News Service.
- Hurricane Eta — another slow-moving, severe storm of the type predicted by climate models — [left at least 50 people dead and caused widespread flooding and damage](#) as it passed through Central America before heading back out to the Caribbean Sea. David Agren has the story for Catholic News Service.

Here's some of what's new in other climate news:

- If you're wondering whether the Trump administration will take advantage of the 10 weeks before Biden's inauguration to push through last-minute regulatory changes, you might want to keep an eye on the New York University law school's Midnight Watch, which is [tracking so-called "midnight actions"](#) involving climate, energy and environmental issues.
- At E&E News, Jean Chemnick takes a look at [Biden's climate policy advisers and their recommendations](#) for nearly a dozen White House offices and federal government agencies, which include a new four-year Climate Ambition Agenda. And Justin Worland at Time takes a closer look at how Biden could [take stronger action on the climate crisis](#) even without the support of Congress.
- A shout-out to the Catholic Diocese of Richmond, Virginia, whose program to help parishes switch to rooftop solar energy [won a project-of-the-year award](#) from Solar Builder magazine, as Chris Crowell reports for the publication. Of course, [you read about that first on EarthBeat](#), where NCR environment correspondent Brian Roewe took a close look at how the Catholic Energies program works and its growing popularity in the Old Dominion.
- And in Costa Rica, scientists are nurturing an underwater coral nursery, an effort they hope will help [revive the country's dying coral reefs](#) and provide vital information about how to protect and restore other marine ecosystems, Ashleigh Papp reports for Mongabay.com.

Upcoming events:

What would a just global economy, rooted in integral ecology and responsive to the cry of the earth and the cry of the poor, look like? The Vatican is bringing together young people and economists to explore that question from various angles from Nov. 19-21. The event, originally scheduled to be held in Assisi, Italy, St. Francis' birthplace, has gone online, and parts will be livestreamed.

For more information about this and other events, see our [Upcoming Events page](#).

Closing beat:

What are you wondering about climate science or the ways in which people are responding to the changes that lie ahead for our planet and its inhabitants? What

would you like to know about the spirituality that sustains those working for policy change and environmental justice? [Send us your Burning Question](#), and we'll find the answers.
